## CHAPTER 6

6.1 (a) The Minitab output of the three regressions is shown below.

In the model involving $\mathrm{x}_{1}$ alone, the hypothesis $\beta_{1}=0$ can not be rejected. This indicates that $\mathrm{x}_{1}$ by itself is not important.
Similarly, in the model involving $x_{2}$ alone, $x_{2}$ by itself is not significant ( $\beta_{2}=0$ can not be rejected).
The model $\mathrm{y}=\beta_{0}+\beta_{1} \mathrm{x}_{1}+\beta_{2} \mathrm{x}_{2}+\varepsilon$ leads to a large $\mathrm{R}^{2}=0.794$, and the partial t tests for $\beta_{1}=0$ and $\beta_{2}=0$ are significant. This indicates that $\mathrm{x}_{1}$ helps explain y at fixed levels of $x_{2}$; and $x_{2}$ helps explain $y$ at fixed levels of $x_{1}$.
This example is instructive as it shows that regressors may be insignificant when studied alone, but taken jointly they may help explain a large part of the variability. It provides an example where stepwise procedures lead to different solutions. Forward selection and stepwise regression would not include any variables, whereas backward elimination would select the model with both regressors. This shows that it is preferable to look at all possible regressions. Note that $\mathrm{x}_{1}$ and $\mathrm{x}_{2}$ are correlated ( $\mathrm{r}=$ 0.734).

Abraham/Ledolter: Chapter 6 6-1

(b) Observation \#2 (with $x_{1}=43, x_{2}=223$ and $y=480$ ) is unusual and somewhat different than the rest. We remove this observation and refit the three models. The results are similar, with the model with both $\mathrm{X}_{1}$ and $\mathrm{x}_{2}$ leading to the best representation.

The regression equation is
$Y=287-17.6$ X1 + 5.18 X2

6.3 Vector of fitted values and residuals: $\hat{\boldsymbol{\mu}}=\mathrm{H} \boldsymbol{y} ; \boldsymbol{e}=(\mathrm{I}-\mathrm{H}) \boldsymbol{y}=\left(\mathrm{I}-\mathrm{X}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime}\right) \boldsymbol{y}$, where $\mathrm{X}=[\mathbf{1}, \boldsymbol{x}]$ is the n 22 matrix, and $\boldsymbol{\beta}=\left(\beta_{0}, \beta_{1}\right)^{\prime}$.
True model: $\boldsymbol{y}=\beta_{0} \mathbf{1}+\beta_{1} \boldsymbol{x}_{1}+\beta_{2} \boldsymbol{x}_{2}+\boldsymbol{\varepsilon}$ where $\boldsymbol{x}_{2}^{\prime}=\left(\mathrm{x}_{1}^{2}, \ldots, \mathrm{x}_{\mathrm{n}}^{2}\right)$

$$
\begin{aligned}
\mathrm{E}(\boldsymbol{e}) & =\left(\mathrm{I}-\mathrm{X}^{\prime}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime}\right) \mathrm{E}(\boldsymbol{y})=(\mathrm{I}-\mathrm{H})\left[\mathrm{X} \boldsymbol{\beta}+\beta_{2} \boldsymbol{x}_{2}+\mathrm{E}(\boldsymbol{\varepsilon})\right]=(\mathrm{I}-\mathrm{H}) \mathrm{X} \boldsymbol{\beta}+\beta_{2}(\mathrm{I}-\mathrm{H}) \boldsymbol{x}_{2} \\
& =\beta_{2}(\mathrm{I}-\mathrm{H}) \boldsymbol{x}_{2} \text { since }(\mathrm{I}-\mathrm{H}) \mathrm{X}=\mathrm{O}
\end{aligned}
$$

6.4
(a) $\mathrm{E}(\hat{\boldsymbol{\mu}})=\mathrm{E}(\mathrm{X} \hat{\boldsymbol{\beta}})=\mathrm{XE}(\hat{\boldsymbol{\beta}})=\mathrm{X} \boldsymbol{\beta}$
$\mathrm{V}(\hat{\boldsymbol{\mu}})=\mathrm{V}(\mathrm{X} \hat{\boldsymbol{\beta}})=\mathrm{XV}(\hat{\boldsymbol{\beta}}) \mathrm{X}^{\prime}=\mathrm{X}\left(\sigma^{2}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1}\right) \mathrm{X}^{\prime}=\sigma^{2} \mathrm{X}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime}$
(b) $\sum_{\mathrm{i}=1}^{\mathrm{n}} \mathrm{V}\left(\hat{\mu}_{\mathrm{i}}\right)=\sigma^{2} \operatorname{tr}\left(\mathrm{X}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime}\right)=\sigma^{2} \operatorname{tr}\left(\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime} \mathrm{X}\right)=\sigma^{2} \operatorname{tr}(\mathrm{I})=\sigma^{2}(\mathrm{p}+1)$

Hence $\frac{1}{\mathrm{n}} \sum_{\mathrm{i}=1}^{\mathrm{n}} \mathrm{V}\left(\hat{\mu}_{\mathrm{i}}\right)=\frac{(\mathrm{p}+1)}{\mathrm{n}} \sigma^{2}$
(c) $\boldsymbol{a}_{\mathrm{i}}^{\prime} \mathrm{X}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime} \boldsymbol{a}_{\mathrm{i}}=\boldsymbol{a}_{\mathrm{i}}^{\prime} \mathrm{H} \boldsymbol{a}_{\mathrm{i}} \geq 0$ because $\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1}$ is a positive semidefinite matrix. Select $\boldsymbol{a}_{\mathrm{i}}$ as the vector with all components 0 except for a " 1 " in the ith element.
Thus $\mathrm{h}_{\mathrm{ii}} \geq 0$.
H is symmetric and idempotent. $\mathrm{H}=\mathrm{HH}$ implies $\mathrm{h}_{\mathrm{ii}}=\mathrm{h}_{\mathrm{ii}}^{2}+\sum_{\mathrm{j} \neq \mathrm{i}}^{\mathrm{n}} \mathrm{h}_{\mathrm{ij}}^{2} \geq 0$ and $\sum_{\mathrm{j} \neq \mathrm{i}}^{\mathrm{n}} \mathrm{h}_{\mathrm{ij}}^{2}=\mathrm{h}_{\mathrm{ii}}\left(1-\mathrm{h}_{\mathrm{ii}}\right) \geq 0$. Since $\mathrm{h}_{\mathrm{ii}} \geq 0$, we find that $\left(1-\mathrm{h}_{\mathrm{ii}}\right) \geq 0$ and $\mathrm{h}_{\mathrm{ii}} \leq 1$.
(d) We can parameterize the model as $\boldsymbol{y}=\mathbf{1} \alpha+\mathrm{V} \boldsymbol{\beta}_{*}+\varepsilon$ where $\alpha=\beta_{0}+\beta_{1} \overline{\mathrm{x}}_{1}+\ldots+\beta_{\mathrm{p}} \overline{\mathrm{x}}_{\mathrm{p}}, \mathrm{V}=\left[\boldsymbol{v}_{1}, \boldsymbol{v}_{2}, \ldots \boldsymbol{v}_{\mathrm{p}}\right]$ contains the mean corrected regressors $\boldsymbol{v}_{\mathrm{j}}=\boldsymbol{x}_{\mathrm{j}}-\overline{\mathrm{x}}_{\mathrm{j}} \mathbf{1}, \overline{\mathrm{x}}_{\mathrm{j}}$ is the average of the elements of the vector $\boldsymbol{x}_{\mathrm{j}}$, and $\boldsymbol{\beta}_{*}$ is the vector $\boldsymbol{\beta}$ without the element $\beta_{0}$.
Note that $\mathrm{X}=[\mathbf{1}, \mathrm{V}]$ and $\mathbf{1}^{\prime} \boldsymbol{v}_{\mathrm{j}}=0$, for $\mathrm{j}=1,2, \ldots, \mathrm{p}$. Hence

$$
\begin{aligned}
& X^{\prime} X=\left[\begin{array}{cc}
\mathrm{n} & 0 \\
0 & \mathrm{~V}^{\prime} \mathrm{V}
\end{array}\right],\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1}=\left[\begin{array}{cc}
\mathrm{n}^{-1} & 0 \\
0 & \left(\mathrm{~V}^{\prime} \mathrm{V}\right)^{-1}
\end{array}\right], \text { and } \\
& \mathrm{H}=\left[\begin{array}{ll}
\mathbf{1} & \mathrm{V}
\end{array}\right]\left[\begin{array}{cc}
\mathrm{n}^{-1} & 0 \\
0 & \left(\mathrm{~V}^{\prime} \mathrm{V}\right)^{-1}
\end{array}\right]\left[\begin{array}{c}
\mathbf{1}^{\prime} \\
\mathrm{V}^{\prime}
\end{array}\right]=\left[\mathrm{n}^{-1} \mathbf{1 1 ^ { \prime } + \mathrm { V } ( \mathrm { V } ^ { \prime } \mathrm { V } ) ^ { - 1 } \mathrm { V } ^ { \prime } ] .}\right.
\end{aligned}
$$

The matrix $\mathrm{H}^{*}=\mathrm{V}\left(\mathrm{V}^{\prime} \mathrm{V}\right)^{-1} \mathrm{~V}^{\prime}$ is symmetric and idempotent; we have shown in 6.4(c) that its diagonal elements $h_{i i}^{*}$ are between 0 and 1 . Hence the ith diagonal element of $\mathrm{H}, \mathrm{h}_{\mathrm{ii}}=\mathrm{n}^{-1}+\mathrm{h}_{\mathrm{ii}}^{*} \geq \mathrm{n}^{-1}$.
(e) Both $\hat{\boldsymbol{\beta}}$ and $\tilde{\boldsymbol{\beta}}$ are solutions of $\left(\mathrm{X}^{\prime} \mathrm{X}\right) \boldsymbol{\beta}=\mathrm{X}^{\prime} \boldsymbol{y}$. Hence $\left(\mathrm{X}^{\prime} \mathrm{X}\right) \hat{\boldsymbol{\beta}}=\mathrm{X}^{\prime} \boldsymbol{y}$ and $\left(\mathrm{X}^{\prime} \mathrm{X}\right) \tilde{\boldsymbol{\beta}}=\mathrm{X}^{\prime} \boldsymbol{y}$, and $\left(\mathrm{X}^{\prime} \mathrm{X}\right)(\hat{\boldsymbol{\beta}}-\tilde{\boldsymbol{\beta}})=\mathbf{0}$.
Let $\hat{\boldsymbol{\mu}}=\mathrm{X} \hat{\boldsymbol{\beta}}, \tilde{\boldsymbol{\mu}}=\mathrm{X} \tilde{\boldsymbol{\beta}}$, and $\hat{\boldsymbol{\mu}}-\tilde{\mu}=\mathrm{X}(\hat{\boldsymbol{\beta}}-\tilde{\boldsymbol{\beta}})$.
$\sum_{\mathrm{i}=1}^{\mathrm{n}}\left(\hat{\mu}_{\mathrm{i}}-\tilde{\mu}_{\mathrm{i}}\right)^{2}=(\hat{\boldsymbol{\mu}}-\tilde{\boldsymbol{\mu}})^{\prime}(\hat{\boldsymbol{\mu}}-\tilde{\boldsymbol{\mu}})=(\hat{\boldsymbol{\beta}}-\tilde{\boldsymbol{\beta}})^{\prime} \mathrm{X}^{\prime} \mathbf{X}(\hat{\boldsymbol{\beta}}-\tilde{\boldsymbol{\beta}})=(\hat{\boldsymbol{\beta}}-\tilde{\boldsymbol{\beta}})^{\prime} \mathbf{0}=0$
The sum of squares is zero if and only if $\left(\hat{\mu}_{\mathrm{i}}-\tilde{\mu}_{\mathrm{i}}\right)=0$ for all i. Hence $\hat{\boldsymbol{\mu}}=\tilde{\boldsymbol{\mu}}$.
6.5
(a) We need to show: $\left(\mathrm{I}+\alpha \boldsymbol{v} \boldsymbol{w}^{\prime}\right)\left[\mathrm{I}-\left(\frac{\alpha}{1+\alpha \boldsymbol{v}^{\prime} \boldsymbol{w}}\right) \boldsymbol{v \boldsymbol { w } ^ { \prime }}\right]=\mathrm{I}$

The left hand side is given by

$$
\begin{aligned}
\text { LHS }=\mathrm{I}+\alpha v w^{\prime} & -\left[\frac{\alpha\left[v w^{\prime}+\alpha v w^{\prime} v w^{\prime}\right]}{1+\alpha v^{\prime} w}\right] \\
& =\mathrm{I}+\alpha v w^{\prime}-\left[\frac{\alpha}{1+\alpha v^{\prime} \boldsymbol{w}}\right]\left[1+\alpha v^{\prime} w\right] v w^{\prime}=\mathrm{I}+\alpha v w^{\prime}-\alpha v w^{\prime}=\mathrm{I}
\end{aligned}
$$

(b) For full rank matrices with the same dimension: (CD) ${ }^{-1}=\mathrm{D}^{-1} \mathrm{C}^{-1}$. Hence $\left(\mathrm{A}+\boldsymbol{w} \boldsymbol{w}^{\prime}\right)^{-1}=\left[\mathrm{A}\left(\mathrm{I}+\mathrm{A}^{-1} \boldsymbol{w} \boldsymbol{w}^{\prime}\right)\right]^{-1}=\left(\mathrm{I}+\mathrm{A}^{-1} \boldsymbol{w} \boldsymbol{w}^{\prime}\right)^{-1} \mathrm{~A}^{-1}$.
Let $\mathrm{A}^{-1} \boldsymbol{w}=\boldsymbol{v}$ and $\alpha=1$. Then
$\left(\mathrm{A}+\boldsymbol{w} \boldsymbol{w}^{\prime}\right)^{-1}=\left(\mathrm{I}+\boldsymbol{v} \boldsymbol{w}^{\prime}\right)^{-1} \mathrm{~A}^{-1}=\left[\mathrm{I}-\left(\frac{1}{1+\boldsymbol{v}^{\prime} \boldsymbol{w}}\right) \boldsymbol{v} \boldsymbol{w}^{\prime}\right] \mathrm{A}^{-1}=\mathrm{A}^{-1}-\frac{\mathrm{A}^{-1} \boldsymbol{w} \boldsymbol{w}^{\prime} \mathrm{A}^{-1}}{1+\boldsymbol{w}^{\prime} \mathrm{A}^{-1} \boldsymbol{w}}$.
(c) (i) Note that $\mathrm{X}_{1}=\left[\begin{array}{c}\mathrm{X} \\ \boldsymbol{w}^{\prime}\end{array}\right] ;\left(\mathrm{X}_{1}^{\prime} \mathrm{X}_{1}\right)^{-1}=\left(\mathrm{X}^{\prime} \mathrm{X}+\boldsymbol{w} \boldsymbol{w}^{\prime}\right)^{-1}$

Let $X^{\prime} \mathrm{X}=\mathrm{A}$. Then
Abraham/Ledolter: Chapter 6

$$
\left(\mathrm{X}_{1}^{\prime} \mathrm{X}_{1}\right)^{-1}=\mathrm{A}^{-1}-\frac{\mathrm{A}^{-1} \boldsymbol{w} \boldsymbol{w}^{\prime} \mathrm{A}^{-1}}{1-\boldsymbol{w}^{\prime} \mathrm{A}^{-1} \boldsymbol{w}}=\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1}-\frac{\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w} \boldsymbol{w}^{\prime}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1}}{1-\boldsymbol{w}^{\prime}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w}}
$$

(ii) $\hat{\boldsymbol{\beta}}_{1}=\left(\mathrm{X}_{1}^{\prime} \mathrm{X}_{1}\right)^{-1} \mathrm{X}_{1}^{\prime} \boldsymbol{y}_{1}=\left(\mathrm{X}^{\prime} \mathrm{X}+\boldsymbol{w} \boldsymbol{w}^{\prime}\right)^{-1}\left(\mathrm{X} \boldsymbol{y}+\boldsymbol{w} \mathrm{y}_{\mathrm{n}+1}\right)=$

$$
=\hat{\boldsymbol{\beta}}-\frac{\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w} \boldsymbol{w}^{\prime} \hat{\boldsymbol{\beta}}}{1-\boldsymbol{w}^{\prime}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w}}+\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w} \mathrm{y}_{\mathrm{n}+1}-\frac{\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w} \boldsymbol{w}^{\prime}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w} \mathrm{y}_{\mathrm{n}+1}}{1-\boldsymbol{w}^{\prime}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w}}
$$

Define the scalar $\mathrm{h}=\boldsymbol{w}^{\prime}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w}$. Then

$$
\begin{aligned}
\hat{\boldsymbol{\beta}}_{1} & =\hat{\boldsymbol{\beta}}-\frac{\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w} \boldsymbol{w}^{\prime}}{1-\mathrm{h}} \hat{\boldsymbol{\beta}}+\frac{\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w}(1-\mathrm{h}) \mathrm{y}_{\mathrm{n}+1}}{1-\mathrm{h}} \\
& =\hat{\boldsymbol{\beta}}+\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \boldsymbol{w}\left(\mathrm{y}_{\mathrm{n}+1}-\frac{1}{1-\mathrm{h}} \boldsymbol{w}^{\prime} \hat{\boldsymbol{\beta}}\right)
\end{aligned}
$$

6.6 The estimate of $\boldsymbol{\beta}$ in the model with all the x 's, $\boldsymbol{y}=\mathrm{X} \boldsymbol{\beta}+\boldsymbol{\varepsilon}$, is

$$
\hat{\boldsymbol{\beta}}=\left[\begin{array}{c}
\hat{\boldsymbol{\beta}}_{(\mathrm{K})} \\
\hat{\beta}_{\mathrm{K}}
\end{array}\right]=\left[\begin{array}{cc}
\tilde{\mathrm{X}}^{\prime} \tilde{\mathrm{X}} & \tilde{\mathrm{X}}^{\boldsymbol{x}_{\mathrm{K}}} \\
\boldsymbol{x}_{\mathrm{K}}^{\prime} \tilde{\mathrm{X}} & \boldsymbol{x}_{\mathrm{K}}^{\prime} \boldsymbol{x}_{\mathrm{K}}
\end{array}\right]^{-1}\left[\begin{array}{l}
\tilde{\mathrm{X}}^{\prime} \boldsymbol{y} \\
\boldsymbol{x}_{\mathrm{K}}^{\prime} \boldsymbol{y}
\end{array}\right]
$$

where the $\mathrm{nx}(\mathrm{k}-1)$ matrix $\widetilde{\mathrm{X}}$ is as defined in the hint and where $\hat{\boldsymbol{\beta}}_{(\mathrm{K})}$ denotes the vector of estimates $\hat{\boldsymbol{\beta}}$ without the element $\hat{\beta}_{\mathrm{K}}$.
Using the results on the inverse of a partitioned matrix given in the appendix of Chapter 6, we obtain
$\hat{\beta}_{\mathrm{K}}=\frac{\boldsymbol{x}_{\mathrm{K}}^{\prime}(\mathrm{I}-\tilde{\mathrm{H}}) \boldsymbol{y}}{\boldsymbol{x}_{\mathrm{K}}^{\prime}(\mathrm{I}-\tilde{\mathrm{H}}) \boldsymbol{x}_{\mathrm{K}}}$ where $\tilde{\mathrm{H}}=\mathrm{I}-\tilde{\mathrm{X}}\left(\tilde{\mathrm{X}}^{\prime} \tilde{\mathrm{X}}\right)^{-1} \tilde{\mathrm{X}}^{\prime}$ is an idempotent matrix; $\tilde{\mathrm{H}} \tilde{H}=\tilde{\mathrm{H}}$.

In step 1 , when we regress $\boldsymbol{y}$ on $\tilde{X}$ we obtain the vector of residuals $\boldsymbol{r}=(\mathrm{I}-\tilde{\mathrm{H}}) \boldsymbol{y}$. In step 2 , when we regress $\boldsymbol{x}_{\mathrm{K}}^{\prime}$ on $\tilde{X}$ we obtain the vector of residuals $\boldsymbol{u}=(\mathrm{I}-\tilde{\mathrm{H}}) \boldsymbol{x}_{\mathrm{K}}^{\prime}$ Note that the means of the residual vectors $\boldsymbol{r}$ and $\boldsymbol{u}$ are zero. Hence the slope of the regression of $\boldsymbol{r}$ on $\boldsymbol{u}$ in step 3 is
$\tilde{\beta}_{\mathrm{K}}=\boldsymbol{u}^{\prime} \boldsymbol{r} / \boldsymbol{u}^{\prime} \boldsymbol{u}=\frac{\boldsymbol{x}_{\mathrm{K}}^{\prime}(\mathrm{I}-\tilde{\mathrm{H}})(\mathrm{I}-\tilde{\mathrm{H}}) \boldsymbol{y}}{\boldsymbol{x}_{\mathrm{K}}^{\prime}(\mathrm{I}-\tilde{\mathrm{H}})(\mathrm{I}-\tilde{\mathrm{H}}) \boldsymbol{x}_{\mathrm{K}}}=\boldsymbol{x}_{\mathrm{K}}^{\prime}(\mathrm{I}-\tilde{\mathrm{H}}) \boldsymbol{y} / \boldsymbol{x}_{\mathrm{K}}^{\prime}(\mathrm{I}-\tilde{\mathrm{H}}) \boldsymbol{x}_{\mathrm{K}}=\hat{\beta}_{\mathrm{K}}$
6.7
(a) True. For a correct model, $\operatorname{Cov}(\boldsymbol{e}, \hat{\boldsymbol{\mu}})=\mathrm{O}$, and a plot of the residuals $\mathrm{e}_{\mathrm{i}}$ against the fitted values $\hat{\mu}_{\mathrm{i}}$ should show no association. However, $\operatorname{Cov}(\boldsymbol{e}, \boldsymbol{y})=\sigma^{2}(\mathrm{I}-\mathrm{H})$; the correlation makes the interpretation of the plot of $e_{i}$ against $y_{i}$ difficult.
(b) Not true. Outliers should be scrutinized, but not necessarily rejected.
(c) True
6.8 (a) 5; (b) 2; (c) 4; (d) 1
6.9 (a) True; (b) True; (c) False; (d) False; (e) False
6.10 (d) True. Linear regression of $\ln (\mathrm{y})$ on $\ln \left(\mathrm{x}_{1}\right)$ and $\ln \left(\mathrm{x}_{2}\right)$ to estimate $\beta_{1}$ and $\beta_{2}$.
6.11 (a) No; (b) No; (c) No; (d) No; (e) True
6.12 A (Palm Beach); B (Broward); C (Dade); D (Pasco)
6.13 Consider the stock price data lenzing and refer to Exercise 10.9
6.14 Note that the pressures are equally spaced on the logarithmic scale, suggesting that the investigator expected equal changes in the ratio of pressures to produce equal changes in the tearing factor. This suggests that a logarithmic transformation of pressure (x) may be appropriate.
Scatter plots of y against $\mathrm{x}, \mathrm{y}$ against $\ln (\mathrm{x}), \ln (\mathrm{y})$ against x , and $\ln (\mathrm{y})$ against $\ln (\mathrm{x})$ were constructed. For a data set of such small size, the choice among the various transformations is difficult. Here we consider a model of y on $\ln (\mathrm{x})$.

## R-output

|  | Estimate | Std. Error | t value | $\operatorname{Pr}(>\|t\|)$ |
| :--- | ---: | ---: | ---: | ---: |
| (Intercept) | 152.451 | 10.493 | 14.529 | $2.19 \mathrm{e}-11$ |
| $\ln \mathrm{x}$ | -10.604 | 2.453 | -4.322 | 0.000411 |

Residual standard error: 5.378 on 18 degrees of freedom Multiple R-Squared: 0.5093, Adjusted R-squared: 0.482 F-statistic: 18.68 on 1 and 18 DF, p-value: 0.0004105

Because of the replications it is possible to calculate a test for lack of fit. The Fstatistic is small and no lack of fit is indicated. The residual plot suggests that the variability in the response may not be the same at all settings of pressure. However, this fact is difficult to assess with a small data set such as this.

| Minitab output and test for lack of fit |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

| 1.00 | 11.960 | 0.912 |

$s(\lambda)$ is the residual standard error and $\mathrm{R}^{2}$ is the coefficient of determination in the regression of $\frac{y^{\lambda}-1}{\lambda\left(\bar{y}_{\mathrm{g}}\right)^{\lambda-1}}$ on x .
6.16 The regression shows that neither of the two variables can be omitted from the model. The residual plot indicates no major model violations. Also the scatter plots of the residuals against the two explanatory variables are unremarkable. The case with the largest Cook's distance is case \# 48 with $\mathrm{x}_{1}=2.35, \mathrm{x}_{2}=56$ and $\mathrm{y}=72$ (Cook = 0.27)

The regression equation is
$Y=23.0+23.6$ X1 - 0.715 X2

6.17 Scatter plots indicate that a linear regression of rigidity on elasticity and density is appropriate. Partial output from R is given below:

Coefficients:

|  | Estimate | Std. Error | t value | $\operatorname{Pr}(>\|\mathrm{t}\|)$ |
| :--- | ---: | ---: | ---: | ---: |
| (Intercept) | -1.8300 | 121.1577 | -0.015 | 0.988 |
| x1 | 3.4179 | 0.7925 | 4.313 | $8.21 \mathrm{e}-05$ |
| x2 | 19.5830 | 3.2851 | 5.961 | $3.08 \mathrm{e}-07$ |

Residual standard error: 185.9 on 47 degrees of freedom Multiple R-Squared: 0.8119, Adjusted R-squared: 0.8039 F-statistic: 101.4 on 2 and 47 DF, p-value: < 2.2e-16

Residual diagnostics indicate that observation \# 40 has large influence (Cook $=$ 0.572 ). This observation should be scrutinized.

We remove this observation and refit the model on the reduced data set. The Minitab results are shown below. The residual plot is unremarkable, except perhaps for a large positive and a large negative residual. However, the Cook influence from the case with the large positive residual (original case \#46) is not particularly worrisome (Cook $=0.215$ ).

Exercise 6.17

### 6.18

(a) The correlation between liver weight (LW) and body weight (BW) is 0.5 . This is also confirmed by the plot of LW versus BW.
(b) Pair-wise scatter plots of y against the three regressors show very little association. We regress y (dose in liver) on $\mathrm{BW}=$ body weight, $\mathrm{LW}=$ liver weight and $\mathrm{DL}=$ dose. The regression results indicate that BW and DL are significant, which is somewhat surprising as we have not seen strong associations in the pair-wise scatter plots.
Case \# 3 (with $\mathrm{BW}=190, \mathrm{LW}=9.0$, Dose $=1.00$, and $\mathrm{y}=0.56$ ) is a very influential observation (Cook $=0.930$ ). This case should be scrutinized. Dropping this case from the data set, leads to the regression results shown below. Neither one of the three regressors is significant ( F -statistic $=0.10$ ), which supports the conclusion from the earlier scatter plots.

### 6.19

Pair-wise scatter plots of y against the two regressors show moderate association and an outlying case (case $\# 17$ with $x_{1}=26.8, x_{2}=58$ and $y=168$ ). The regression results shown below indicate a significant regressor $x_{1}$ and $R^{2}=0.482$. The influence of case $\# 17$ is large (Cook $=0.838$ ). Removing this case from the data set leads to the revised estimates. Variable $x_{2}$ can be dropped from the model. Inorganic phosphorus explains about half of the variation in plant phosphorus $\left(R^{2}=0.519\right)$.

### 6.20

The scatter plot of vocabulary (y) against age (x) indicates an approximate linear relationship, with the exception of case \#1 (Age = 1; Vocabulary = 3). Fitting the linear regression on age leads to the results shown below. The first case exerts large influence (Cook = 1.126). Omitting this observation leads to the revised estimates. The fit improves; the standard deviation of the residuals decreases from 116.7 to 81.45. Also the residual plots improve.

R output (all observations)
Coefficients:

|  | Estimate | Std. Error | t value | $\operatorname{Pr}(>\|\mathrm{t}\|)$ |
| :--- | ---: | ---: | ---: | ---: |
| (Intercept) | -763.86 | 88.25 | -8.656 | $2.47 \mathrm{e}-05$ |

F-statistic: 910.7 on 1 and 7 DF, p-value: 1.131e-08
```

### 6.21

Scatter plot of $\ln (y)$ against $\ln (x)$ shows a linear association with three outlying observations (brachiosaurus, diplodocus, and triceratops). Omitting these three cases and fitting the linear model to the reduced data set leads to an adequate fit. Estimated equation: $\hat{\mu}=2.15+0.752 \ln (\mathrm{x}) ; \mathrm{R}^{2}=0.922 ; \mathrm{s}=0.726$. The two observations with the largest positive residuals and the largest Cook influence are human (stand. residual $=2.72 ;$ Cook $=0.174$ ) and Rhesus monkey (stand. residual $=$ 2.25; Cook $=0.119$ ).

### 6.22

Estimated equation: $\hat{\mu}=74.319-2.089$ Conc +0.430 Ratio -0.372 Temp; $R^{2}=0.939 ; s=0.74 ; F($ lack of fit $)=7.44 ; p$-value $=0.036$; indication of lack of fit.

Analysis of Variance

| Source | DF | SS | MS | F | P |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Regression | 3 | 92.304 | 30.768 | 56.17 | 0.000 |
| Residual Error | 11 | 6.026 | 0.548 |  |  |
| $\quad$ Lack of Fit | 7 | 5.596 | 0.799 | 7.44 | 0.036 |
| $\quad$ Pure Error | 4 | 0.430 | 0.108 |  |  |
| Total | 14 | 98.329 |  |  |  |

Run \#2 (Conc = 1, Ratio = -1,Temp = -1; Yield = 73.9) influential, with large Cook’s distance. This run should be investigated. Without this run, no lack of fit.
6.23 Scatter plots of $y, \ln (y), \sqrt{y}, 1 / y$ against $x$ indicate that the square root transformation works best to (i) achieve a linear relationship, and (ii) stabilize the variance.

The regression results for the square root transformation of the response are shown below. The residual plot shows no remaining patterns. The normal probability plot of the residuals is adequate.

| The regression equation is <br> sqrt(Stopping) $=0.918+0.253$ Speed |  |  |  |  |

Exercise 6.23

Exercise 6.23: Normal probability plot

The transformation parameter of the Box-Cox family is estimated by regressing the transformed response $\frac{\mathrm{y}^{\lambda}-1}{\lambda\left(\overline{\mathrm{y}}_{\mathrm{g}}\right)^{\lambda-1}}$ on x , and finding the $\lambda$ that minimizes the error sum of squares or the residual standard error $s(\lambda)$. The results show that the square root transformation is the appropriate transformation to use.

| $\lambda$ | $\mathrm{s}(\lambda)$ |
| :--- | ---: |
| -1.00 | 40.90 |
| -0.75 | 27.11 |
| -0.50 | 18.49 |
| -0.25 | 12.99 |
| 0.00 ln | 9.49 |
| 0.25 | 7.61 |
| 0.50 sqrt | 7.34 |
| 0.75 | 8.77 |
| 1.00 | 11.80 |

6.24 From the equation for the volume of a cylinder, one can expect a model of the form $\mathrm{V}=\alpha\left(\mathrm{x}_{1}\right)^{2} \mathrm{x}_{2}$, or after taking the logarithm, $\ln (\mathrm{V})=\beta_{0}+\beta_{1} \ln \left(\mathrm{x}_{1}\right)+\beta_{2} \ln \left(\mathrm{x}_{2}\right)$. The fit of this model is quite good; $\mathrm{R}^{2}=0.626$. The residual plot is adequate, and even the largest Cook's influence ( 0.224 for case \#18) is not particularly worrisome.

```
The regression equation is
lny = - 6.63 + 1.98 lnx1 + 1.12 lnx2
\begin{tabular}{lrrrr} 
Predictor & Coef & SE Coef & T & P \\
Constant & -6.6316 & 0.7998 & -8.29 & 0.000 \\
lnx1 & 1.98265 & 0.07501 & 26.43 & 0.000 \\
